# Testa WP2: Sampling

## **Part 1**

- Goal of WP2
- A description of lots, sampling and testing
- Studies to provide estimates of the things that effect sampling

## **Part 2**

- How to produce plans to meet goals for detection
- Some plans
- QA for plans

## Goal of WP2

- Estimate the size of sources of variation that effect sampling and testing
- Produce sampling plans for the detection of quarantine pests and pathogens in seed lots
- Plans have associated reliable estimates for Limit of Detection for pest and pathogens in lots

## What is sampling for?

- Testa is focussing on quarantine pathogens.
- Any finding leads to rejection
- The pest or pathogen should not be present at any level
- We want sampling and testing to provide high confidence that if a pest or pathogen is present at all it must be at a low level.

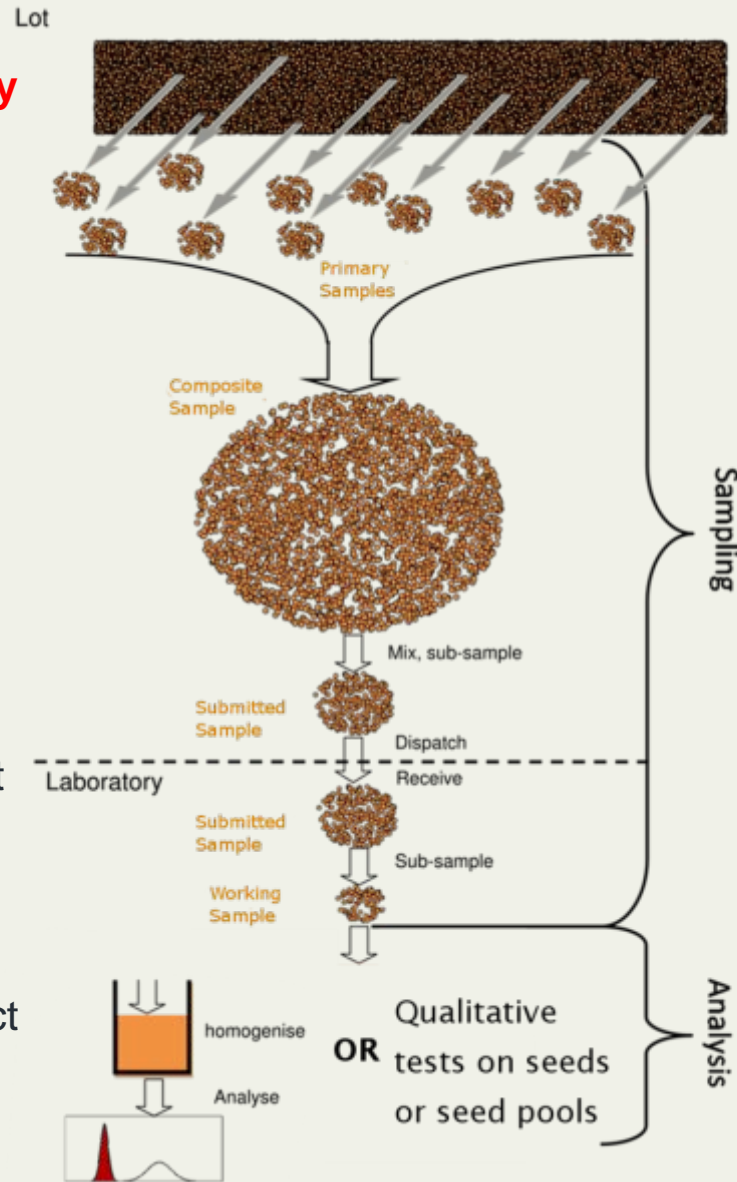

## What is sampling for?

- Testa is focussing on quarantine pathogens.
- Any finding leads to rejection
- We want sampling and testing to provide **high confidence** that if a pest or pathogen is present at all it must be at a low level.
- We want sampling and test plans with a *reliably known* low **limit of detection** for pests and pathogens.

## Designing plans is easy if...

- Assume that seed lots are homogenous.
- Assume that the detection method is reliable
- There is a well known simple relation between sample size and limit of detection and confidence in the limit (eg ISPM31)

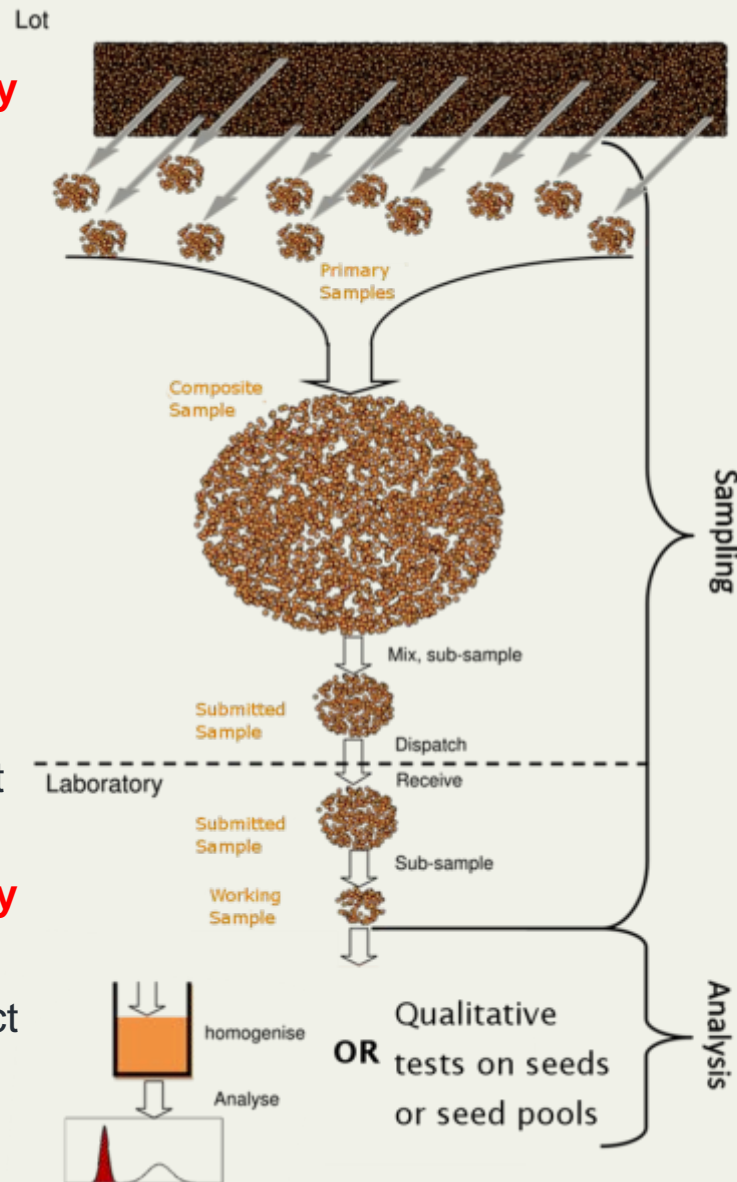

Level of pathogen may vary in different parts of the lot

We may want to detect low levels

We may have imperfect detection

Level of pathogen may vary in different parts of the lot

We may want to detect low levels

Level of pathogen may vary "between seeds"

We may have imperfect detection

Level of pathogen may vary in different parts of the lot

Take enough primary samples

We may want to detect low levels

Make the working sample large enough

We may have imperfect detection

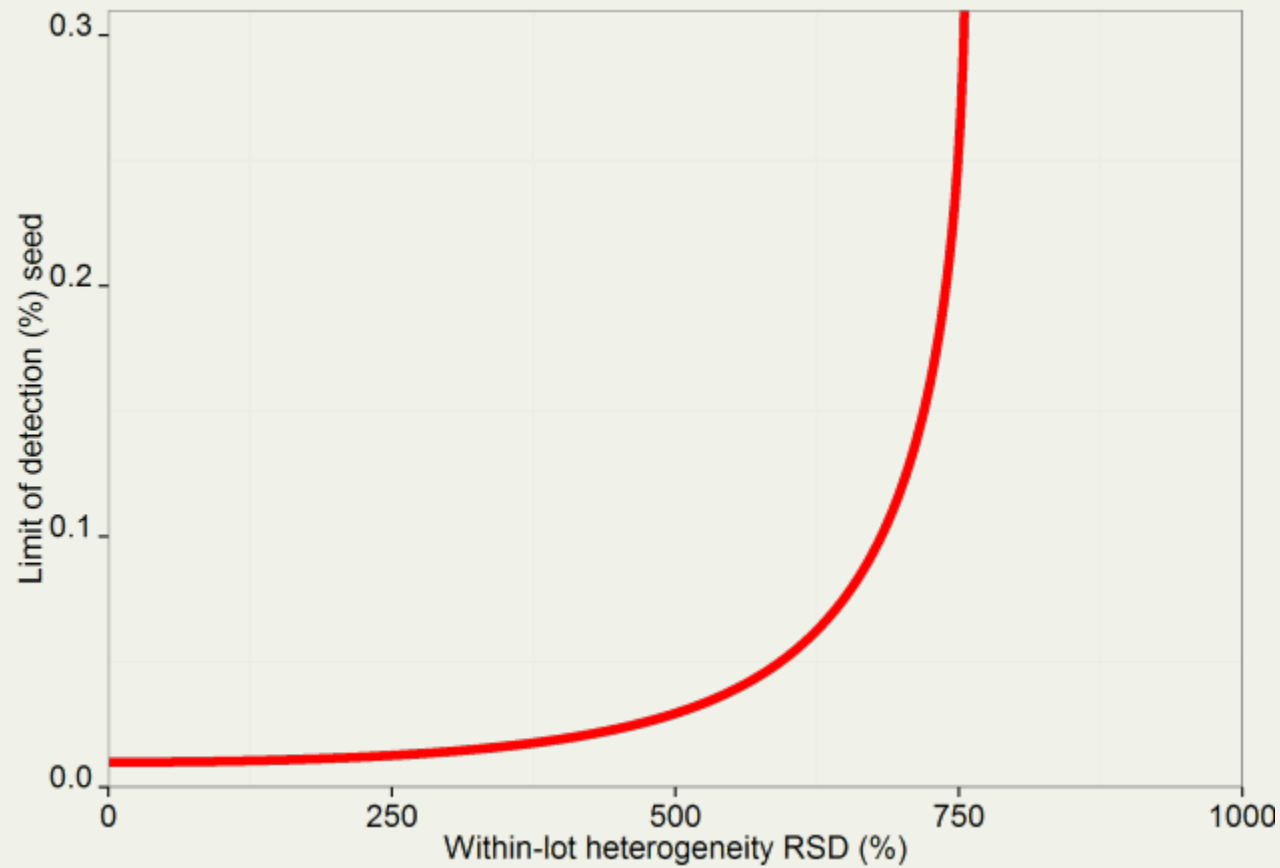

Modify method / replicate testing

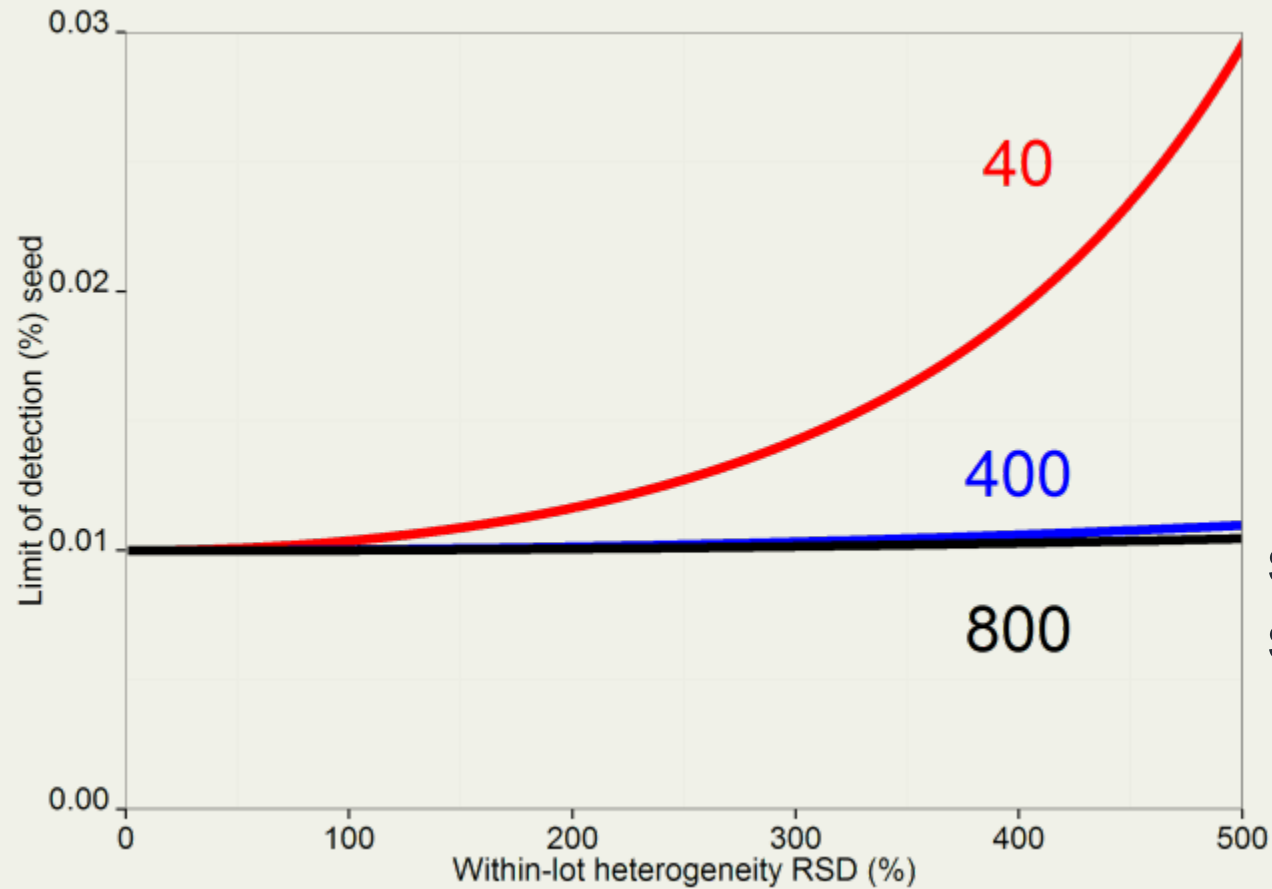

# Factors the effect the sampling plan

| FACTOR                              | SAMPLING PLAN   |
|-------------------------------------|---|
| Variation in different parts of lot | Number of primary samples   |
| Variation at small scale (seeds)    | Size of working sample  |
| Average level of pathogen           | Size of analytical aliquot  |
| LOD of analytical method            | Size of working sample / Size of analytical aliquot / Replication |

# Effect of primary sample variation

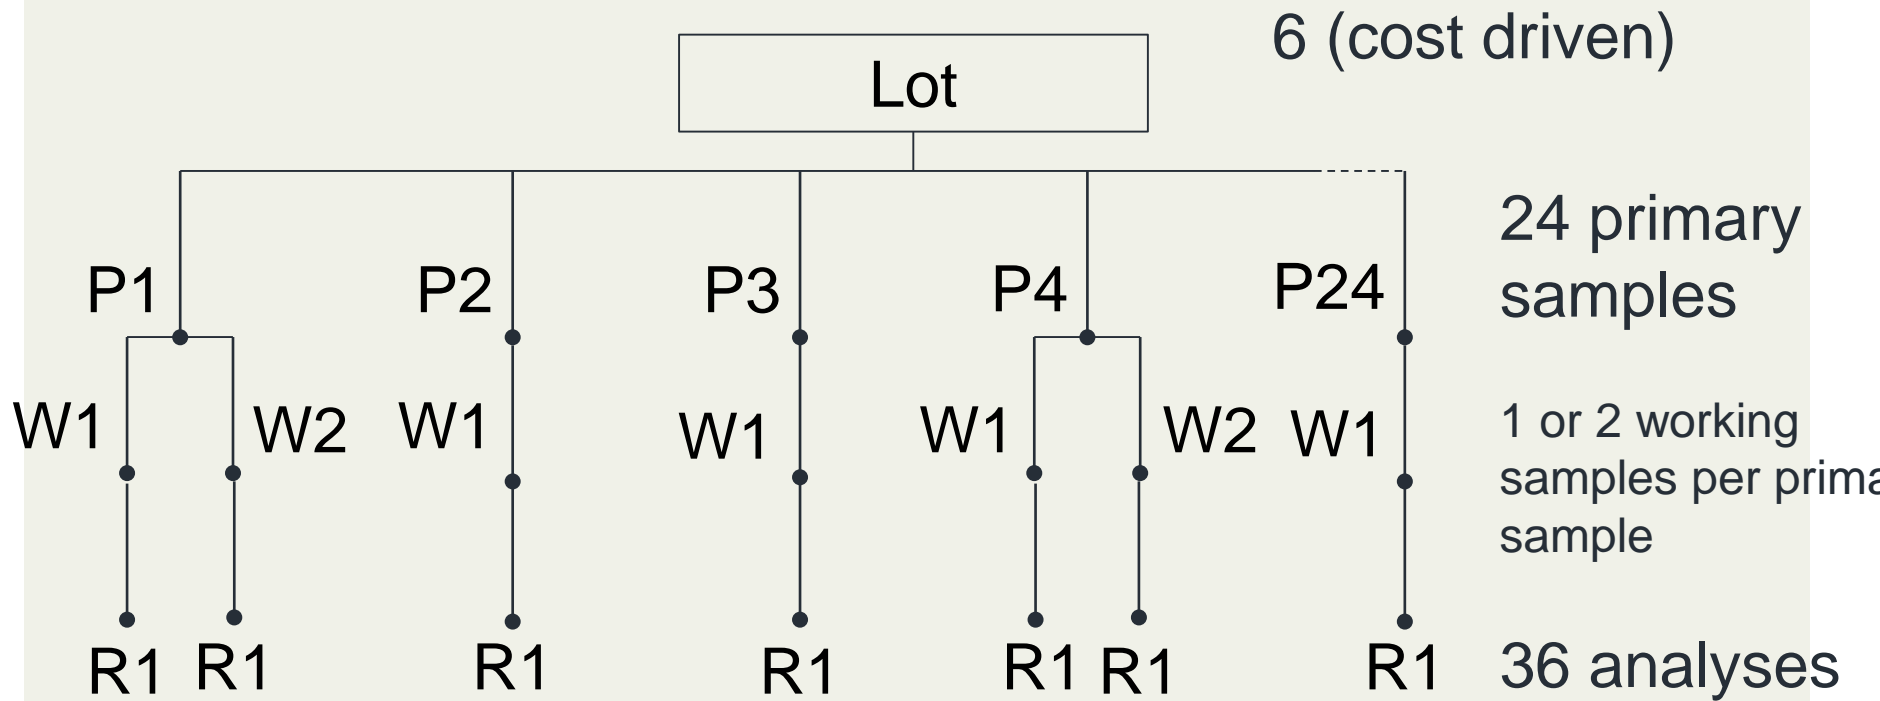

For 30 000  
seed working  
sample

## Testa studies on lots

- Four case studies.
- Fusarium species in wheat
- Ditylenchus sp. In field bean
- Xcc in brassica
- Tilletia in wheat
- Six lots per study
  
- Other scenarios using available information

# Lot study design

## Ditylenchus: normal method

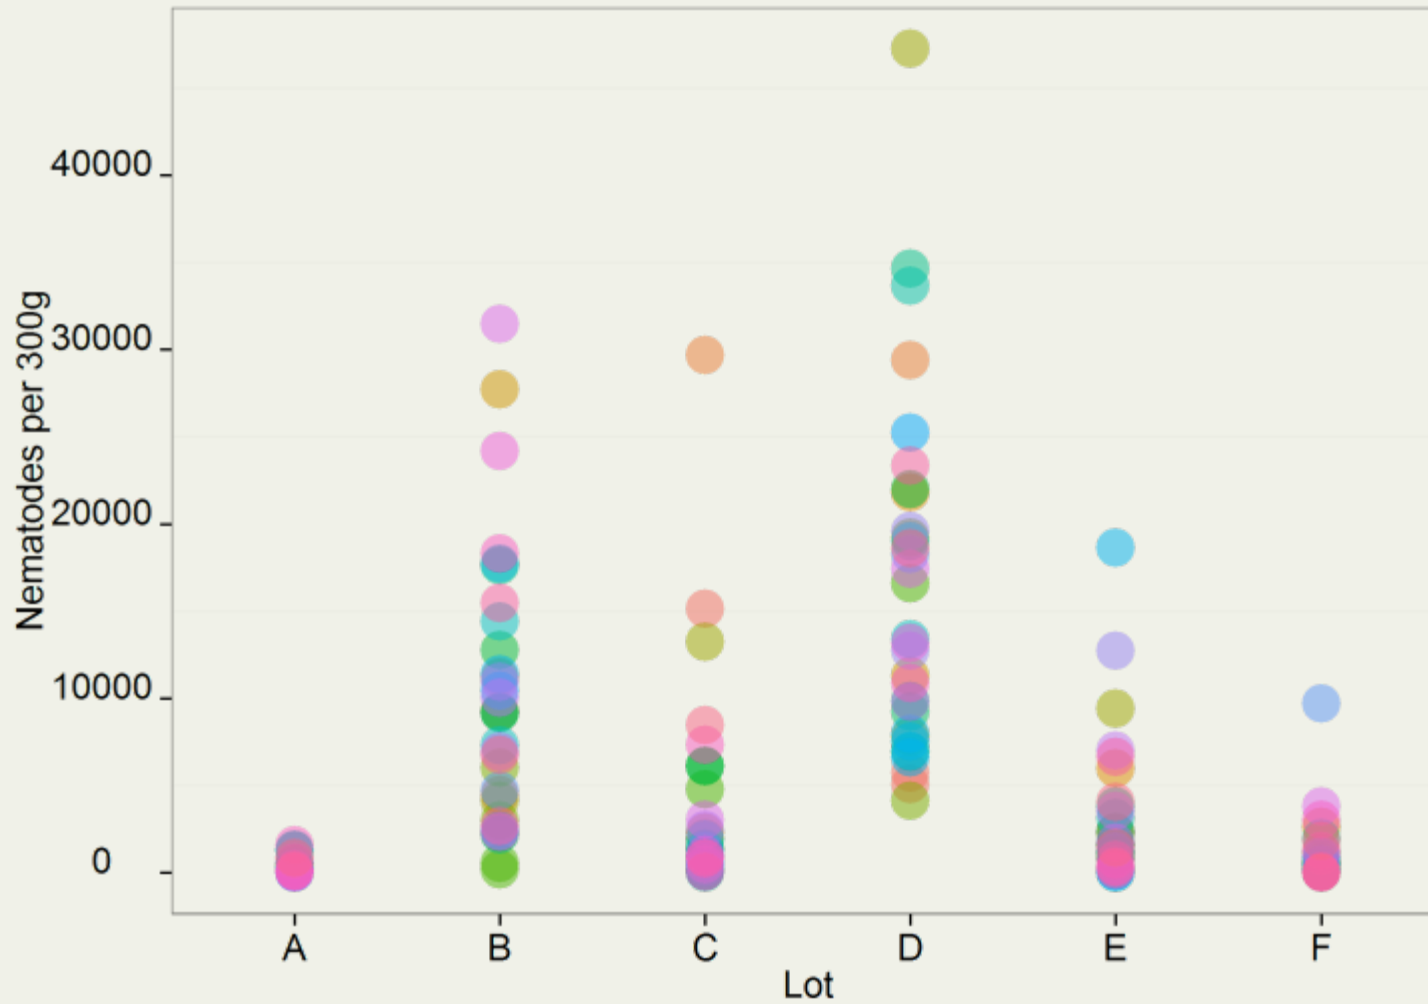

- Take 300g working sample from the submitted sample
- Extract into water
- Decant and examine water by microscopy
- Report positive if any are found  
(QUALITATIVE TEST)

## Ditylenchus: lot study method

- Take 300g working sample from the submitted sample. For half of the samples take duplicate 300g working samples (REPLICATION)
- Extract into water
- Decant and examine water by microscopy
- If nematodes are found, count them and report the number (QUANTITATIVE TEST)

# Ditylenchus sp.- results

Level of pathogen may vary in different parts of the lot

Take enough primary samples

We may want to detect low levels

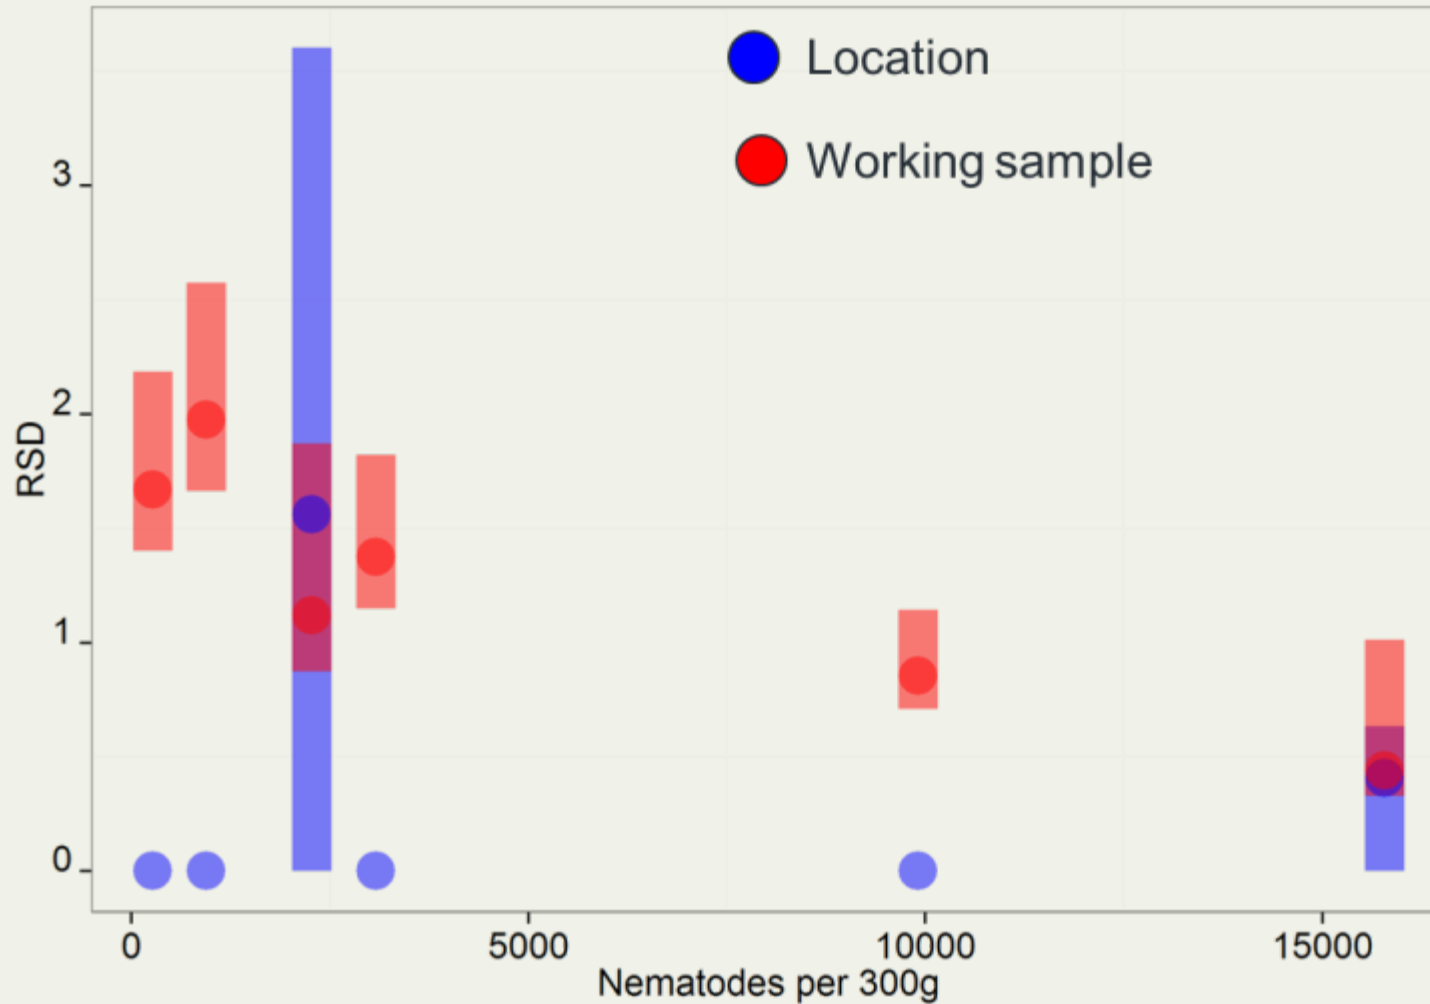

Make the working sample large enough

We may have imperfect detection

Modify method / replicate testing

# Between location and between working sample variation

## Estimates of factors that effect sampling: XCC

- Results expressed as cfu per sample
- Sparse results (lots of zeroes) with some very high values
- Analysed as between-sample variation. Assumed to be driven by between seed variation

# Estimates of factors that effect sampling: XCC

| Lot | Mean cfu per 2 seeds | Between 100-seed-sample RSD |
|-----|----------------------|-----------------------------|
| A   | 0.0750               | 3.69                        |
| B   | 0.175                | 1.89                        |
| C   | 228                  | 7.71                        |

# Effect of detection: method tilletia

- Two methods
  - Microscopy of an aliquot of extract: effective sample size = 9.07 seeds
  - Centrifugation and examination of whole extract effective sample size = 900 seed
- But during experimental comparison recovery from centrifuged samples is only 19.7% of the expected value: effective sample size 177.3 seeds

# Effect of detection method: general approach

- Eg: For XCC take 10 000 seeds working sample soak in 100 ml, take 100 $\mu$ l aliquot for testing
- A perfect test for presence:
  - Sample size for effect of between seed variation = 10 000 seeds
  - Sample size for detecting low mean level in seeds = 10 seeds

# Effect of detection method: general approach

- Eg: For XCC take 10 000 seeds working sample soak in 100 ml, take 100 $\mu$ l aliquot for testing
- A test for presence with LOD of 10 cfu (95% probability)
  - Sample size for effect of between seed variation = 10 000 seeds
  - Sample size for detecting low mean level in seeds = 2.59 seeds
- A test for presence with LOD of 100 cfu (95% probability)
  - Sample size for effect of between seed variation = 10 000 seeds
  - Sample size for detecting low mean level in seeds = 0.295 seeds

# Effect of detection method: general approach

- Eg: For XCC take  $S$  seeds working sample soak in  $V_1$ , take  $V_2$  aliquot for testing
- Test for presence with LOD of  $L$  cfu ( $p_d$ % probability)
  - Sample size for effect of between seed variation =  $S$  seeds
  - Sample size  $E$  for detecting low mean level in seeds :

$$E = S \frac{V_2}{V_1} (1 - (1 - p_d)^{1/L})$$

# QUESTIONS ON STUDIES?

Level of pathogen may vary in different parts of the lot

Take enough primary samples

We may want to detect low levels

Make the working sample large enough

We may have imperfect detection

Modify method / replicate testing

# Elements of the plans: fusariums

$$\text{primary samples} \geq \left( \frac{R_L}{0.18} \right)^2$$

$L_D$  Estimated numerically from beta-binomial distribution

|            |   |
|------------|---|
| $L_D$      | <b>limit of detection of sampling plan proportion of infected seeds; 95% probability of detection</b> |
| $R_L$      | up to RSD=0.75  |
| R          | Qualitative: infected, not infected   |
| <b>S</b>   | <b>Number of seeds in working sample</b>  |
| $V_1$      | 1   |
| $V_2$      | 1   |
| $p_a, L_a$ | 100% probability of detection   |

# Elements of plans: fusariums

*primary samples: 20*

---

| Working sample size<br>(seeds) | Limit of detection (proportion<br>infected seeds) |
|--------------------------------|---|
| 100                            | 3.1%  |
| 150                            | 2.1%  |
| 200                            | 1.5%  |
| 300                            | 1.0%  |
| 400                            | 0.78%   |

---

## QA for sampling plans

Produce INDEPENDENT duplicate working samples.

- Test each working sample using the more quantitative version of available tests.
- Proportion positive or number of spore/cfu/pest for each working sample should be equivalent
- Standard approaches are:
- Little R.J.A., 1989, Testing the equality of two independent binomial proportions, *The American Statistician*, 43(4), 283-288 [in "Slippery Approach to Bayesianism"]
- Przyborowski J and Wilenski H, 1940, Homogeneity of Results in Testing Samples from Poisson Series: With an Application to Testing Clover Seed for Dodder, *Biometrika*, 31(3-4), 313-323

# Examples of QA results that show unexpected variation

## Counting pests, spores cfu

| Lower count | Higher count |
|-------------|--------------|
| 0           | 8            |
| 1           | 11           |
| 2           | 13           |
| 3           | 15           |
| 4           | 17           |
| 5           | 19           |
| 6           | 20           |
| 7           | 22           |
| 8           | 24           |
| 9           | 25           |
| 10          | 27           |

## Counting positive sub-samples

| Number of subsamples | Lower number of positives | Higher number of positives |
|----------------------|---------------------------|----------------------------|
| 4                    | 0                         | 4                          |
| 5                    | 0                         | 5                          |
| 6                    | 0                         | 6                          |
| 6                    | 1                         | 6                          |
| 7                    | 0                         | 7                          |
| 7                    | 1                         | 7                          |
| 7                    | 2                         | 7                          |
| 7                    | 0                         | 6                          |
| 7                    | 1                         | 6                          |

# Testa sampling WP

- Provides estimate of LOD against sampling effort for a number of specific scenarios.
- Provides some methods that can be used to make estimates of LOD and sampling effort for any scenario.
- Integrates the effects of sampling and analysis
- Testing lots in enough detail to estimate parameters can be expensive
- Getting hold of the right lots can be challenging
